

A GUI or graphical user interface is a certain way to use a computer by doing things like clicking on a picture or buttons and even icons. For most people they use GUI in their everyday life. They use it on their computers, phones and their tablets. An example of this is when you click on an app you are using GUI. GUIs are most of the time very easy to learn since you can see all of the different options on your screen.

A CLI or command-line interface works a little different compared to GUI. Instead of just clicking on an icon, the user must type certain commands into their computer. An example of this is when someone types a command to open a folder. A CLI can be a lot faster for someone who knows what the right commands to use. It can also be hard for those who are just learning how to use it since the commands need to be typed in correctly and you also need to remember all of them.
